Conformément à la terminologie internationale recommandée par l'OMS, les enfants pour lesquels les mesures sont inférieures de deux écarts-types ou plus à la médiane de référence (calculée sur une population-référence d'enfants américains) sont classés comme «gravement malnutris»; ceux dont les mesures se situent entre deux et trois écarts-types sont appelés «modérément malnutris».

Sur 201 enfants de quatre ans nés à Pune avec une insuffisance pondérale, ceux dont le poids de naissance était égal ou inférieur à 2,4 kg présentaient, 30 minutes après l'ingestion d'une dose d'épreuve de glucose, des concentrations sanguines moyennes de 8,1 mM (micromole) de glucose et de 321 pM (picamole) d'insuline, contre 7,5 mM et 289 pM respectivement chez les enfants qui pesaient à la naissance 3 kg ou davantage.
